Abstract

*In-vitro* trial was conducted from November 2017 to April 2018 to determine anthelmintic effects of crude methanolic and ethanolic extracts of the leaf *Bersama abyssinica*. There was no significant ($P > 0.05$) variation between consecutive doses ($50\%, 90\%$ and $95\%$) of methanolic plant extracts on egg hatch activity, whereas ethanolic extracts showed significant variation ($P < 0.05$).

Methanolic extractions of *B. Abyssinia* were $0.15$, $0.308$ and $0.326$mg/ml, while ethanolic extractions were $0.16$, $0.352$ and $0.385$mg/ml respectively.

Current findings, methanolic leaf extracts of the plant were more efficacious than ethanolic leaf extracts. The higher concentration methanolic extract caused significant egg hatching inhibition rate with $95.67\%$, which showed slightly lower effect as compared with that of Albendazole exposed control group ($99.33\%$). Similarly, higher adult *H. contortus* mortality ($76.6\%$) was observed for methanol extract at $8$mg / ml concentrations while for ethanol, it was $60\%$ at the same concentration. Therefore, the present study indicated that the leaf of *B. abyssinica* showed an effect on egg hatch activity and adult mortality. Hence, it can be concluded that leaf can be used as a potential alternative in the discovery of guide compounds that substitute commercially available anthelmintic effects.

However, further *in-vivo* trial should be conducted.
